## Question

You are given three parallel panes of glass. Each pane will transmit $70 \%$, reflect $20 \%$, and absorb $10 \%$ of the light that falls on it.

If a light source is placed on one side of the three panes, what is the total percentage of light that passes through to the other side?

Answer
$343 / 902=\sim 0.380266075388=\sim 38.03 \%$.

## Solution

Let's call the panes of glass 1,2 , and 3 , where the light starts by going through pane 1 first and whose goal is to go through pane 3.

Let:
$a=$ Portion of light that will escape traveling from pane 1 to pane 2.
$b=$ Portion of light that will escape traveling from pane 2 to pane 1 (in other words going backwards).
$\mathrm{c}=$ Portion of light that will escape traveling from pane 2 to pane 3.
$d=$ Portion of light that will escape traveling from pane 3 to pane 2 (in other words going backwards).

We can set up these equations:
$a=0.7 c+0.2 b$
$\mathrm{b}=0.2 \mathrm{a}$
$\mathrm{c}=0.7+0.2 \mathrm{~d}$
$d=0.7 b+0.2 c$

We have four equations and four unknowns, thus we have enough information to solve for all variables, but we only need to for a.

We can set up these equations as a matrix:

| 1 | -0.2 | -0.7 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: |
| -0.2 | 1 | 0 | 0 | 0 |
| 0 | 0 | 1 | -0.2 | 0.7 |
| 0 | -0.7 | -0.2 | 1 | 0 |

Let's call matrix M :

| 1 | -0.2 | -0.7 | 0 |
| ---: | ---: | ---: | ---: |
| -0.2 | 1 | 0 | 0 |
| 0 | 0 | 1 | -0.2 |
| 0 | -0.7 | -0.2 | 1 |

Let's call matrix N :

| 0 | -0.2 | -0.7 | 0 |
| ---: | ---: | ---: | ---: |
| 0 | 1 | 0 | 0 |
| 0.7 | 0 | 1 | -0.2 |
| 0 | -0.7 | -0.2 | 1 |

$\operatorname{determ}(M)=0.902$
$\operatorname{determ}(\mathrm{N})=0.490$
$a=\operatorname{determ}(N) / \operatorname{determ}(M)=0.49 / 0.902=490 / 902=\sim 0.543237251$
However, not all the light makes it to state a. $70 \%$ of it, to be exact. So, the ratio of all the light to the light that escapes pane 3 is 0.7 * 490/902 = 343/902 $=\sim 38.03 \%$.
